Automate Login Test Case with Valid Credentials (Static Data)

This test case represents a basic login scenario using static credentials.

Steps: Identify the pages involved and create their corresponding **Page Object Classes**.

1. *HomePage*:
   - Update this Page Object Class by Adding the Login link element and a method to click on it.
2. *LoginPage*:
   - Create a new `LoginPage` Page Object Class that contains the web elements and methods required to enter the email, enter the password, and click the login button.
3. *MyAccountPage*:
   - If the login is successful, create a new `MyAccountPage` Page Object Class to validate that the "My Account" header is displayed.
   - The method `isMyAccountPageExists()` should not perform direct validation. It should simply return a boolean value or throw an exception if the captured heading text "My Account" is not found.
   - The actual validation (assertion) should be handled in the **test class**, not in the page object.
